Exploration

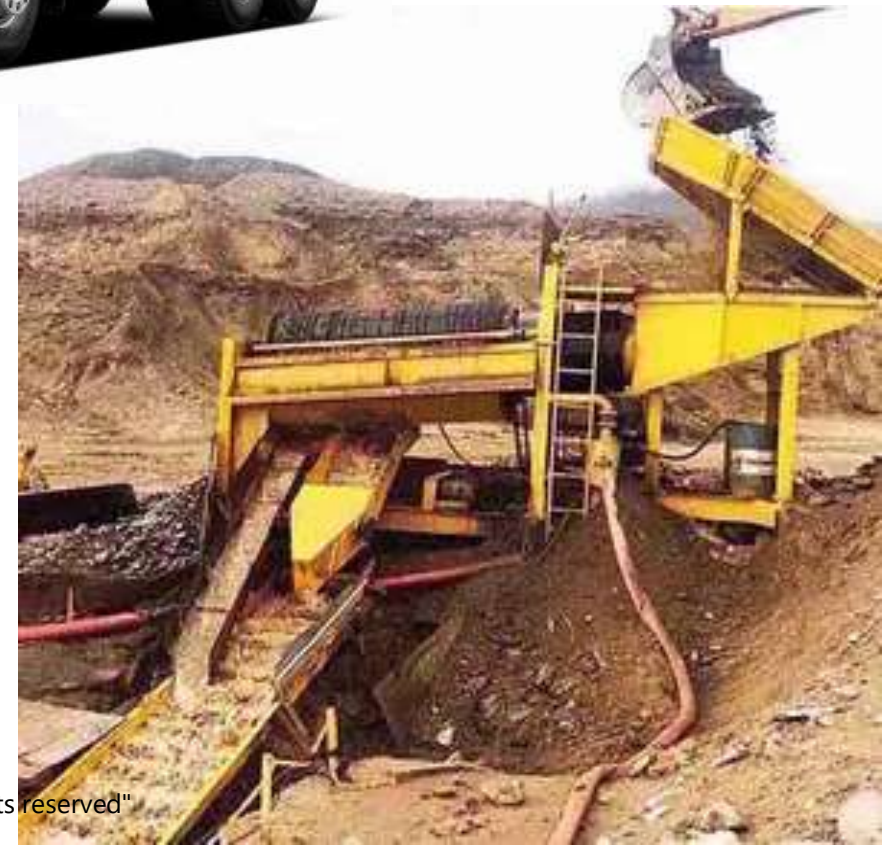

Exploration is the first step, where geologists use satellite imaging, surveys, and drilling to identify and assess gold deposits. This phase confirms the quality and size of a potential site before mining begins.

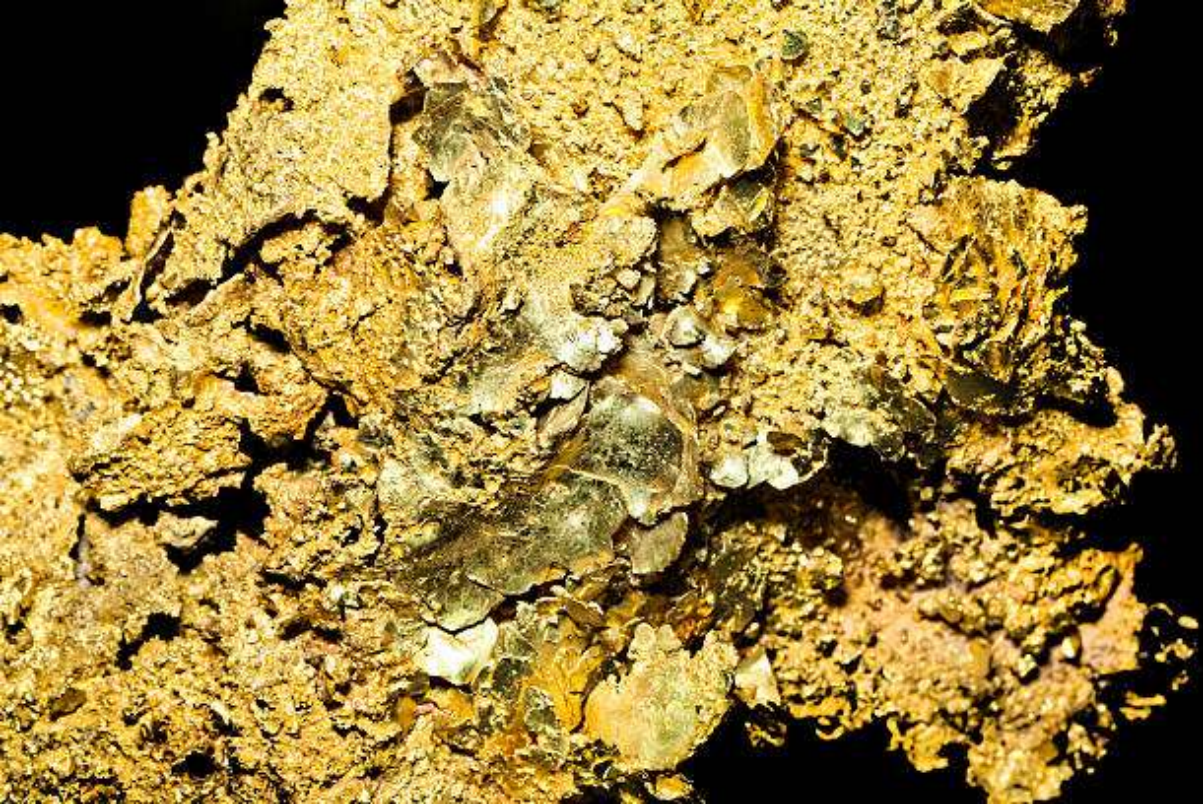

Extraction

In extraction, mining companies choose between open-pit or underground methods based on deposit depth. Open-pit mining removes surface layers for shallow deposits, while underground mining accesses deeper gold through tunnels or shafts.

Processing

The ore is then processed to isolate and purify the gold. Crushing and grinding prepare the ore, while chemical treatments, like cyanidation, separate the gold. Final refining achieves high purity, ready for market.

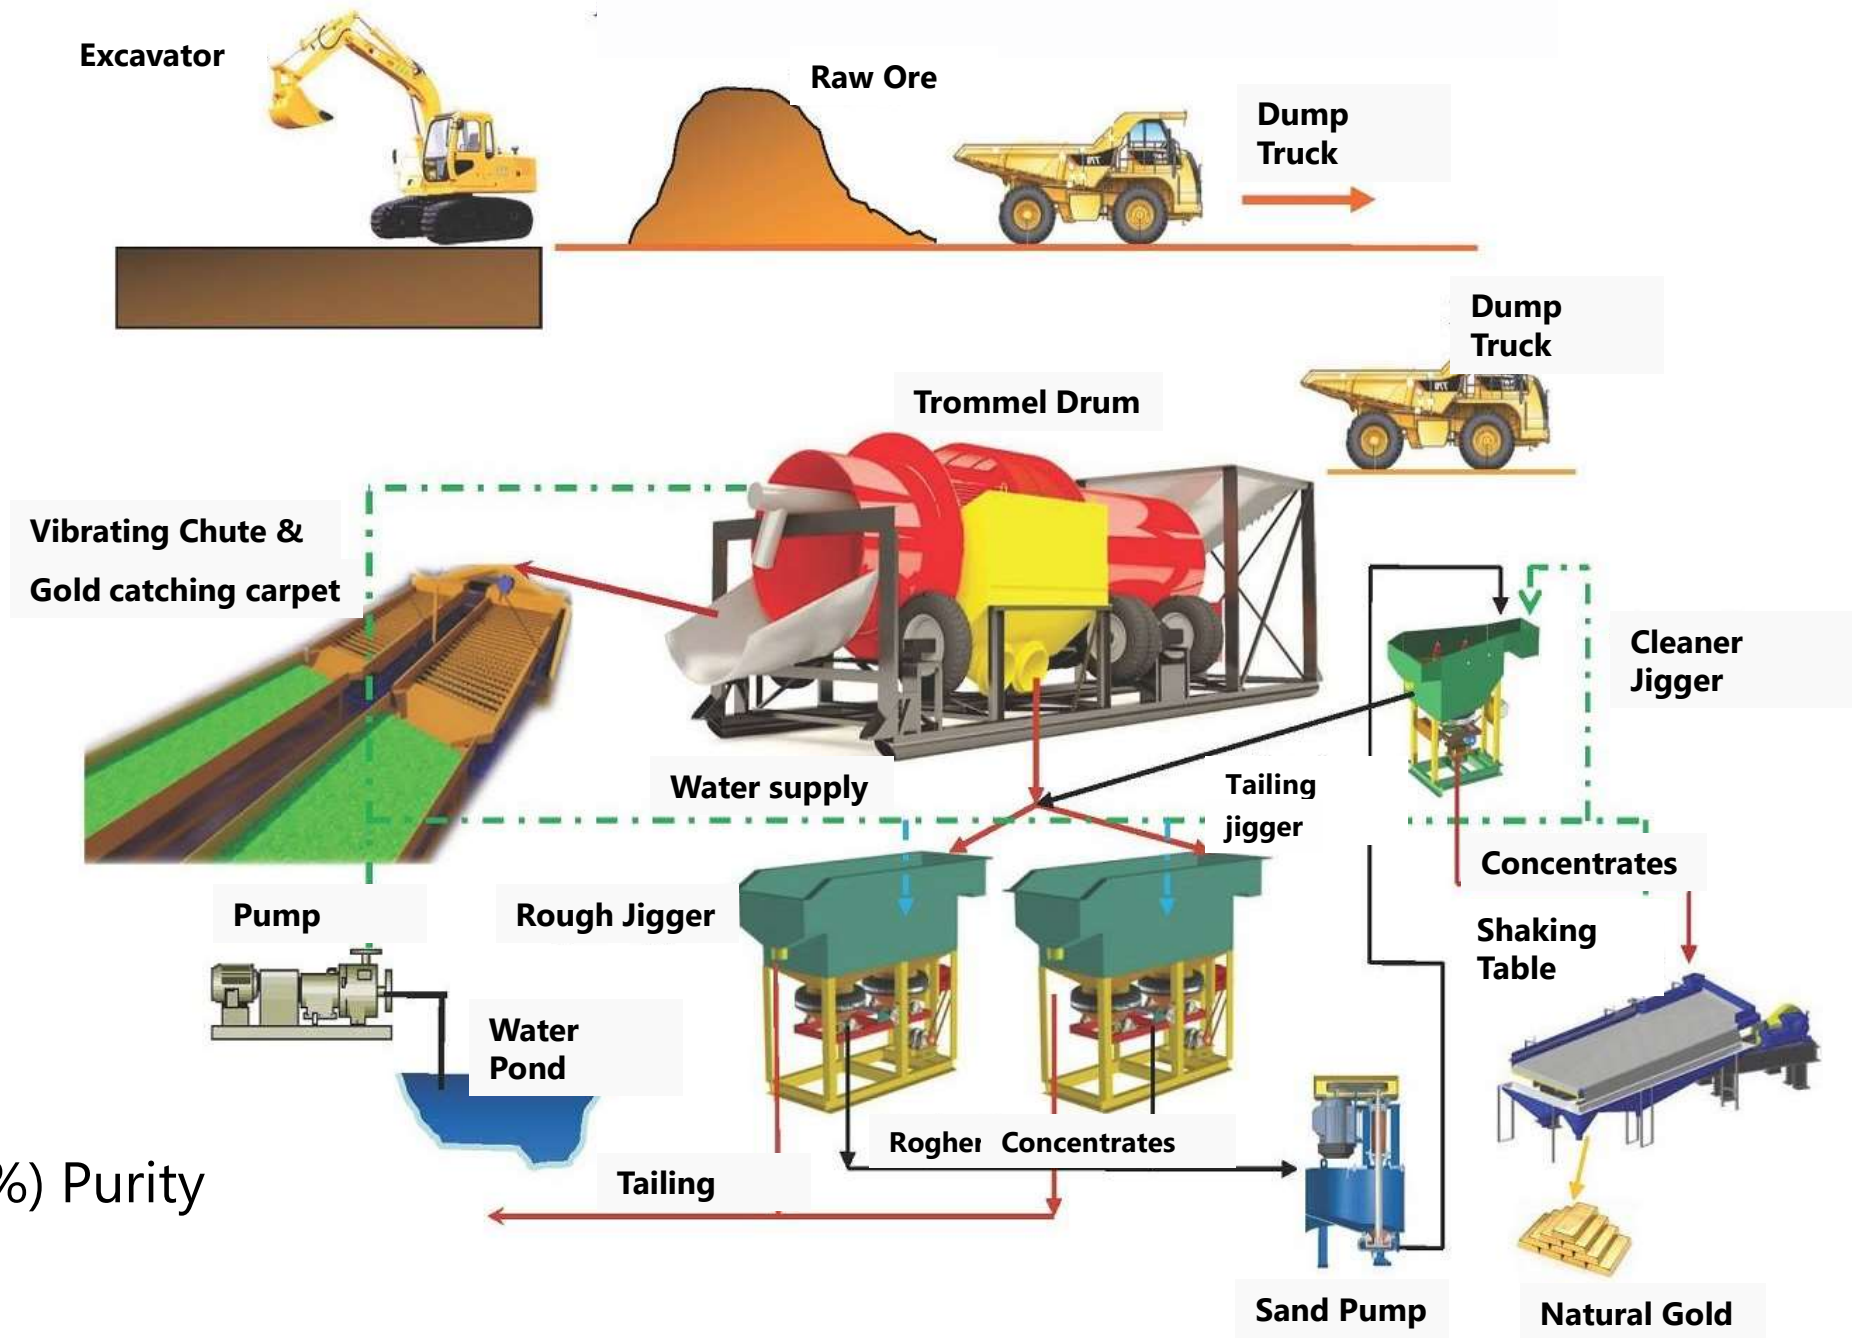

Raw Gold Up to 92% Purity
